# This is the 2-layer neural network workbook for ECE 239AS Assignment #3

Please follow the notebook linearly to implement a two layer neural network.

Please print out the workbook entirely when completed.

We thank Serena Yeung & Justin Johnson for permission to use code written for the CS 231n class (cs231n.stanford.edu). These are the functions in the cs231n folders and code in the jupyer notebook to preprocess and show the images. The classifiers used are based off of code prepared for CS 231n as well.

The goal of this workbook is to give you experience with training a two layer neural network.

```
In [1]: import random
   import numpy as np
   from cs23ln.data_utils import load_CIFAR10
   import matplotlib.pyplot as plt

%matplotlib inline
%load_ext autoreload
%autoreload 2

def rel_error(x, y):
    """ returns relative error """
    return np.max(np.abs(x - y) / (np.maximum(le-8, np.abs(x) + np.abs(y)))))
```

# Toy example

Before loading CIFAR-10, there will be a toy example to test your implementation of the forward and backward pass

```
In [6]: from nndl.neural_net import TwoLayerNet
```

```
In [181]: # Create a small net and some toy data to check your implementations.
          # Note that we set the random seed for repeatable experiments.
          input_size = 4
          hidden_size = 10
          num_classes = 3
          num_inputs = 5
          def init_toy_model():
              np.random.seed(0)
              return TwoLayerNet(input_size, hidden_size, num_classes, std=1e-1)
          def init toy data():
              np.random.seed(1)
              X = 10 * np.random.randn(num_inputs, input_size)
              y = np.array([0, 1, 2, 2, 1])
              return X, y
          net = init_toy_model()
          X, y = init_toy_data()
```

#### **Compute forward pass scores**

```
In [182]: ## Implement the forward pass of the neural network.
           # Note, there is a statement if y is None: return scores, which is why
           # the following call will calculate the scores.
           scores = net.loss(X)
           print('Your scores:')
           print(scores)
           print()
           print('correct scores:')
           correct_scores = np.asarray([
               [-1.07260209, 0.05083871, -0.87253915],
               [-2.02778743, -0.10832494, -1.52641362],
               [-0.74225908, 0.15259725, -0.39578548],
               [-0.38172726, 0.10835902, -0.17328274],
               [-0.64417314, -0.18886813, -0.41106892]])
           print(correct_scores)
           print()
           # The difference should be very small. We get < 1e-7
           print('Difference between your scores and correct scores:')
           print(np.sum(np.abs(scores - correct_scores)))
          Your scores:
           [[-1.07260209
                         0.05083871 -0.87253915
            [-2.02778743 -0.10832494 -1.52641362]
            [-0.74225908 \quad 0.15259725 \quad -0.39578548]
            [-0.38172726 \quad 0.10835902 \quad -0.17328274]
            [-0.64417314 - 0.18886813 - 0.41106892]]
          correct scores:
           [[-1.07260209 \quad 0.05083871 \quad -0.87253915]
            [-2.02778743 -0.10832494 -1.52641362]
            [-0.74225908 \quad 0.15259725 \quad -0.39578548]
            [-0.38172726 \quad 0.10835902 \quad -0.17328274]
            [-0.64417314 -0.18886813 -0.41106892]]
          Difference between your scores and correct scores:
           3.381231233889892e-08
```

#### Forward pass loss

```
In [183]: loss, _ = net.loss(X, y, reg=0.05)
    correct_loss = 1.071696123862817

# should be very small, we get < 1e-12
    print("Loss:",loss)
    print('Difference between your loss and correct loss:')
    print(np.sum(np.abs(loss - correct_loss)))

Loss: 1.071696123862817
    Difference between your loss and correct loss:</pre>
```

0.0

#### **Backward pass**

Implements the backwards pass of the neural network. Check your gradients with the gradient check utilities provided.

```
In [184]: from cs231n.gradient_check import eval_numerical_gradient
          # Use numeric gradient checking to check your implementation of the back
          ward pass.
          # If your implementation is correct, the difference between the numeric
          # analytic gradients should be less than 1e-8 for each of W1, W2, b1, an
          d b2.
          loss, grads = net.loss(X, y, reg=0.05)
          # these should all be less than 1e-8 or so
          for param name in grads:
              print(param name)
              f = lambda W: net.loss(X, y, reg=0.05)[0]
              param grad num = eval numerical gradient(f, net.params[param name],
          verbose=False)
              print('{} max relative error: {}'.format(param_name, rel_error(param_
          grad num, grads[param name])))
          b2
          b2 max relative error: 1.2482651595953946e-09
          W2 max relative error: 2.9632227682005116e-10
          b1 max relative error: 1.7679553783396908e-09
          W1
```

## **Training the network**

Implement neural\_net.train() to train the network via stochastic gradient descent, much like the softmax and SVM.

W1 max relative error: 1.2832908996874818e-09

Final training loss: 0.014497864587765847

# **Classify CIFAR-10**

Do classification on the CIFAR-10 dataset.

```
In [186]: from cs231n.data_utils import load_CIFAR10
          def get CIFAR10 data(num training=49000, num validation=1000, num test=1
          000):
              Load the CIFAR-10 dataset from disk and perform preprocessing to pre
              it for the two-layer neural net classifier. These are the same steps
          as
              we used for the SVM, but condensed to a single function.
              # Load the raw CIFAR-10 data
              cifar10 dir = 'cifar-10-batches-py'
              X train, y train, X test, y test = load CIFAR10(cifar10 dir)
              # Subsample the data
              mask = list(range(num training, num training + num validation))
              X_val = X_train[mask]
              y_val = y_train[mask]
              mask = list(range(num training))
              X_train = X_train[mask]
              y_train = y_train[mask]
              mask = list(range(num_test))
              X_test = X_test[mask]
              y_test = y_test[mask]
              # Normalize the data: subtract the mean image
              mean_image = np.mean(X_train, axis=0)
              X_train -= mean_image
              X val -= mean image
              X_test -= mean_image
              # Reshape data to rows
              X_train = X_train.reshape(num_training, -1)
              X_val = X_val.reshape(num_validation, -1)
              X_test = X_test.reshape(num_test, -1)
              return X train, y train, X val, y val, X test, y test
          # Invoke the above function to get our data.
          X_train, y_train, X_val, y_val, X_test, y_test = get_CIFAR10_data()
          print('Train data shape: ', X_train.shape)
          print('Train labels shape: ', y train.shape)
          print('Validation data shape: ', X_val.shape)
          print('Validation labels shape: ', y_val.shape)
          print('Test data shape: ', X_test.shape)
          print('Test labels shape: ', y_test.shape)
          Train data shape: (49000, 3072)
          Train labels shape: (49000,)
          Validation data shape: (1000, 3072)
          Validation labels shape: (1000,)
          Test data shape: (1000, 3072)
          Test labels shape: (1000,)
```

#### **Running SGD**

If your implementation is correct, you should see a validation accuracy of around 28-29%.

```
In [187]:
          input size = 32 * 32 * 3
          hidden size = 50
          num classes = 10
          net = TwoLayerNet(input size, hidden size, num classes)
          # Train the network
          stats = net.train(X_train, y_train, X_val, y_val,
                      num iters=1000, batch size=200,
                      learning rate=1e-4, learning rate decay=0.95,
                      reg=0.25, verbose=True)
          # Predict on the validation set
          val_acc = (net.predict(X_val) == y_val).mean()
          print('Validation accuracy: ', val acc)
          # Save this net as the variable subopt net for later comparison.
          subopt net = net
          iteration 0 / 1000: loss 2.302757518613176
          iteration 100 / 1000: loss 2.302120159207236
          iteration 200 / 1000: loss 2.2956136007408703
          iteration 300 / 1000: loss 2.2518259043164135

          iteration 700 / 1000: loss 1.9901688623083942
          iteration 800 / 1000: loss 2.002827640124685
```

## **Questions:**

The training accuracy isn't great.

(1) What are some of the reasons why this is the case? Take the following cell to do some analyses and then report your answers in the cell following the one below.

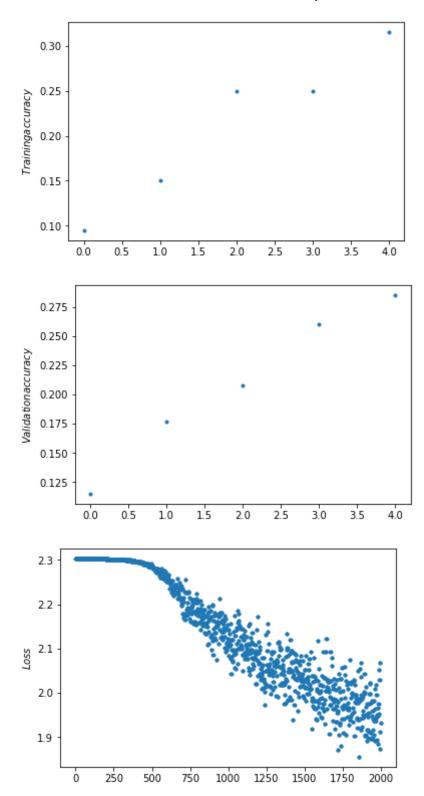

iteration 900 / 1000: loss 1.9465176817856495

(2) How should you fix the problems you identified in (1)?

Validation accuracy: 0.283

```
In [177]: stats['train_acc_history']
Out[177]: [0.155, 0.18, 0.21, 0.295, 0.26]
```

```
In [190]: | # ========= #
       # YOUR CODE HERE:
         Do some debugging to gain some insight into why the optimization
          isn't great.
       # ============= #
       # Plot the loss function and train / validation accuracies
       f = plt.figure()
       ax = f.gca()
       ax.plot(stats['train_acc_history'], '.')
       ax.set_ylabel('$Training accuracy$')
       f = plt.figure()
       ax = f.gca()
       ax.plot(stats['val_acc_history'], '.')
       ax.set_ylabel('$Validation accuracy$')
       f = plt.figure()
       ax = f.gca()
       ax.plot(stats['loss_history'], '.')
       ax.set_ylabel('$Loss$')
       pass
       # ============== #
       # END YOUR CODE HERE
        # ================ #
```

#### **Answers:**

- (1) It seems like there are not enough training iterations, since the accuracy keeps increasing and the loss keeps decreasing per training epoch without showing signs of plateauing.
- (2) To fix this, I will increase the number of iterations.

# **Optimize the neural network**

Use the following part of the Jupyter notebook to optimize your hyperparameters on the validation set. Store your nets as best, net

In [165]: best\_net = None # store the best model into this # =========== # **# YOUR CODE HERE:** Optimize over your hyperparameters to arrive at the best neural network. You should be able to get over 50% validation accuracy. For this part of the notebook, we will give credit based on the # accuracy you get. Your score on this question will be multiplied b y:# min(floor((X - 28%)) / %22, 1)where if you get 50% or higher validation accuracy, you get full # points. # Note, you need to use the same network structure (keep hidden size = 50)! input size = 32 \* 32 \* 3hidden size = 50num classes = 10 best\_net = TwoLayerNet(input\_size, hidden\_size, num\_classes) # Train the network stats = best\_net.train(X\_train, y\_train, X\_val, y\_val, num iters=5000, batch size=200, learning\_rate=1e-3, learning\_rate\_decay=0.95, reg=0.1, verbose=**True**) # ------ # # END YOUR CODE HERE # -----# val\_acc = (best\_net.predict(X\_val) == y\_val).mean() print('Validation accuracy: ', val\_acc)

# **Question:**

(1) What differences do you see in the weights between the suboptimal net and the best net you arrived at?

#### **Answer:**

(1) The best net seems to be less uniform and more variegated than the suboptimal net.

#### **Evaluate on test set**

```
In [174]: test_acc = (best_net.predict(X_test) == y_test).mean()
    print('Test accuracy: ', test_acc)

Test accuracy: 0.523
```

# **Fully connected networks**

In the previous notebook, you implemented a simple two-layer neural network class. However, this class is not modular. If you wanted to change the number of layers, you would need to write a new loss and gradient function. If you wanted to optimize the network with different optimizers, you'd need to write new training functions. If you wanted to incorporate regularizations, you'd have to modify the loss and gradient function.

Instead of having to modify functions each time, for the rest of the class, we'll work in a more modular framework where we define forward and backward layers that calculate losses and gradients respectively. Since the forward and backward layers share intermediate values that are useful for calculating both the loss and the gradient, we'll also have these function return "caches" which store useful intermediate values.

The goal is that through this modular design, we can build different sized neural networks for various applications.

In this HW #3, we'll define the basic architecture, and in HW #4, we'll build on this framework to implement different optimizers and regularizations (like BatchNorm and Dropout).

CS231n has built a solid API for building these modular frameworks and training them, and we will use their very well implemented framework as opposed to "reinventing the wheel." This includes using their Solver, various utility functions, and their layer structure. This also includes nndl.fc\_net, nndl.layers, and nndl.layer\_utils. As in prior assignments, we thank Serena Yeung & Justin Johnson for permission to use code written for the CS 231n class (cs231n.stanford.edu).

# **Modular layers**

This notebook will build modular layers in the following manner. First, there will be a forward pass for a given layer with inputs (x) and return the output of that layer (out) as well as cached variables (cache) that will be used to calculate the gradient in the backward pass.

```
def layer_forward(x, w):
    """ Receive inputs x and weights w """
    # Do some computations ...
    z = # ... some intermediate value
    # Do some more computations ...
    out = # the output

cache = (x, w, z, out) # Values we need to compute gradients
    return out, cache
```

The backward pass will receive upstream derivatives and the cache object, and will return gradients with respect to the inputs and weights, like this:

```
def layer_backward(dout, cache):
    """

    Receive derivative of loss with respect to outputs and cache,
    and compute derivative with respect to inputs.
    """

# Unpack cache values
    x, w, z, out = cache

# Use values in cache to compute derivatives
    dx = # Derivative of loss with respect to x
    dw = # Derivative of loss with respect to w
return dx, dw
```

```

# Linear layers

In this section, we'll implement the forward and backward pass for the linear layers.

The linear layer forward pass is the function affine\_forward in nndl/layers.py and the backward pass is affine\_backward.

After you have implemented these, test your implementation by running the cell below.

#### Affine layer forward pass

Implement affine forward and then test your code by running the following cell.

```
In [14]: # Test the affine forward function
         num inputs = 2
         input\_shape = (4, 5, 6)
         output dim = 3
         input_size = num_inputs * np.prod(input_shape)
         weight_size = output_dim * np.prod(input_shape)
         x = np.linspace(-0.1, 0.5, num=input size).reshape(num inputs, *input sh
         ape)
         w = np.linspace(-0.2, 0.3, num=weight size).reshape(np.prod(input shape
         ), output dim)
         b = np.linspace(-0.3, 0.1, num=output_dim)
         out, _ = affine_forward(x, w, b)
         correct_out = np.array([[ 1.49834967, 1.70660132, 1.91485297],
                                 [ 3.25553199, 3.5141327, 3.77273342]])
         # Compare your output with ours. The error should be around 1e-9.
         print('Testing affine_forward function:')
         print('difference: {}'.format(rel error(out, correct out)))
```

Testing affine\_forward function: difference: 9.769849468192957e-10

## Affine layer backward pass

Implement affine\_backward and then test your code by running the following cell.

```
In [13]: # Test the affine backward function
         x = np.random.randn(10, 2, 3)
         w = np.random.randn(6, 5)
         b = np.random.randn(5)
         dout = np.random.randn(10, 5)
         dx num = eval numerical gradient array(lambda x: affine forward(x, w, b)
         [0], x, dout)
         dw_num = eval_numerical_gradient_array(lambda w: affine_forward(x, w, b)
         [0], w, dout)
         db num = eval numerical gradient array(lambda b: affine forward(x, w, b)
         [0], b, dout)
         _, cache = affine_forward(x, w, b)
         dx, dw, db = affine_backward(dout, cache)
         # The error should be around 1e-10
         print('Testing affine backward function:')
         print('dx error: {}'.format(rel error(dx num, dx)))
         print('dw error: {}'.format(rel_error(dw_num, dw)))
         print('db error: {}'.format(rel_error(db_num, db)))
```

Testing affine\_backward function: dx error: 8.001309275225104e-11 dw error: 9.269057192527758e-11 db error: 8.979786555179818e-12

## **Activation layers**

In this section you'll implement the ReLU activation.

#### **ReLU forward pass**

Implement the relu\_forward function in nndl/layers.py and then test your code by running the following cell.

Testing relu\_forward function: difference: 4.999999798022158e-08

#### ReLU backward pass

Implement the relu\_backward function in nndl/layers.py and then test your code by running the following cell.

```
In [71]: x = np.random.randn(10, 10)
dout = np.random.randn(*x.shape)

dx_num = eval_numerical_gradient_array(lambda x: relu_forward(x)[0], x,
dout)

_, cache = relu_forward(x)
dx = relu_backward(dout, cache)

# The error should be around 1e-12
print('Testing relu_backward function:')
print('dx error: {}'.format(rel_error(dx_num, dx)))
```

Testing relu\_backward function: dx error: 3.275623513586127e-12

# Combining the affine and ReLU layers

Often times, an affine layer will be followed by a ReLU layer. So let's make one that puts them together. Layers that are combined are stored in nndl/layer utils.py.

#### **Affine-ReLU layers**

We've implemented affine\_relu\_forward() and affine\_relu\_backward in nndl/layer\_utils.py. Take a look at them to make sure you understand what's going on. Then run the following cell to ensure its implemented correctly.

```
In [70]: from nndl.layer utils import affine relu forward, affine relu backward
         x = np.random.randn(2, 3, 4)
         w = np.random.randn(12, 10)
         b = np.random.randn(10)
         dout = np.random.randn(2, 10)
         out, cache = affine relu forward(x, w, b)
         dx, dw, db = affine relu backward(dout, cache)
         dx num = eval numerical gradient array(lambda x: affine relu forward(x,
         w, b)[0], x, dout)
         dw_num = eval_numerical_gradient_array(lambda w: affine_relu_forward(x,
         w, b)[0], w, dout)
         db num = eval numerical gradient array(lambda b: affine relu forward(x,
         w, b)[0], b, dout)
         print('Testing affine relu forward and affine relu backward:')
         print('dx error: {}'.format(rel_error(dx_num, dx)))
         print('dw error: {}'.format(rel error(dw num, dw)))
         print('db error: {}'.format(rel_error(db_num, db)))
         Testing affine_relu_forward and affine_relu_backward:
         dx error: 5.174931624442718e-10
         dw error: 1.1918875280563e-10
         db error: 3.275625050801445e-12
```

## **Softmax and SVM losses**

You've already implemented these, so we have written these in layers.py. The following code will ensure they are working correctly.

```
In [69]: num classes, num inputs = 10, 50
         x = 0.001 * np.random.randn(num inputs, num classes)
         y = np.random.randint(num_classes, size=num_inputs)
         dx_num = eval_numerical_gradient(lambda x: svm_loss(x, y)[0], x, verbose
         =False)
         loss, dx = svm_loss(x, y)
         # Test svm loss function. Loss should be around 9 and dx error should be
         1e-9
         print('Testing svm loss:')
         print('loss: {}'.format(loss))
         print('dx error: {}'.format(rel_error(dx_num, dx)))
         dx_num = eval_numerical_gradient(lambda x: softmax_loss(x, y)[0], x, ver
         bose=False)
         loss, dx = softmax loss(x, y)
         # Test softmax loss function. Loss should be 2.3 and dx error should be
          1e-8
         print('\nTesting softmax loss:')
         print('loss: {}'.format(loss))
         print('dx error: {}'.format(rel_error(dx_num, dx)))
         Testing svm_loss:
```

loss: 9.000512776106163 dx error: 8.182894472887002e-10 Testing softmax\_loss: loss: 2.3026368394694394 dx error: 7.804212812258401e-09

# Implementation of a two-layer NN

In  $nndl/fc\_net.py$ , implement the class <code>TwoLayerNet</code> which uses the layers you made here. When you have finished, the following cell will test your implementation.

```
In [79]: N, D, H, C = 3, 5, 50, 7
         X = np.random.randn(N, D)
         y = np.random.randint(C, size=N)
         std = 1e-2
         model = TwoLayerNet(input dim=D, hidden dims=H, num classes=C, weight sc
         ale=std)
         print('Testing initialization ... ')
         W1_std = abs(model.params['W1'].std() - std)
         b1 = model.params['b1']

#### Solver

We will now use the cs231n Solver class to train these networks. Familiarize yourself with the API in cs231n/solver.py. After you have done so, declare an instance of a TwoLayerNet with 200 units and then train it with the Solver. Choose parameters so that your validation accuracy is at least 50%.

```
In [100]: model = TwoLayerNet()
       solver = None
       # ============= #
       # YOUR CODE HERE:
          Declare an instance of a TwoLayerNet and then train
          it with the Solver. Choose hyperparameters so that your validation
          accuracy is at least 50%. We won't have you optimize this further
          since you did it in the previous notebook.
        # -----#
       model = TwoLayerNet(hidden_dims=200, weight_scale=1e-2)
       solver = Solver(model, data,
                   update_rule='sgd',
                   optim_config={
                     'learning_rate': 1e-3,
                   lr decay=0.95,
                   num epochs=20, batch size=200,
                   print_every=100)
       solver.train()
       # =========== #
       # END YOUR CODE HERE
        # ================= #

## **Multilayer Neural Network**

Now, we implement a multi-layer neural network.

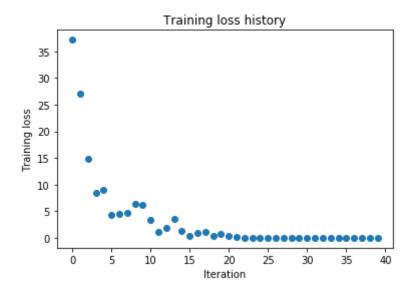

Read through the FullyConnectedNet class in the file nndl/fc net.py.

Implement the initialization, the forward pass, and the backward pass. There will be lines for batchnorm and dropout layers and caches; ignore these all for now. That'll be in assignment #4.

```

This code was originally written for CS 231n at Stanford University (cs231n.stanford.edu). It has been modified in various areas for use in the

ECE 239AS class at UCLA. This includes the descriptions of what code to

implement as well as some slight potential changes in variable names to be

consistent with class nomenclature. We thank Justin Johnson & Serena Yeung for

permission to use this code. To see the original version, please visit

cs231n.stanford.edu.

. . . . . .

# class TwoLayerNet(object):

A two-layer fully-connected neural network. The net has an input dimension of

N, a hidden layer dimension of H, and performs classification over C classes.

We train the network with a softmax loss function and L2 regularization on the

weight matrices. The network uses a ReLU nonlinearity after the first fully

connected layer.

In other words, the network has the following architecture:

input - fully connected layer - ReLU - fully connected layer softmax

The outputs of the second fully-connected layer are the scores for each class.

def \_\_init\_\_(self, input\_size, hidden\_size, output\_size, std=1e-4):

Initialize the model. Weights are initialized to small random values and

biases are initialized to zero. Weights and biases are stored in the

variable self.params, which is a dictionary with the following keys:

W1: First layer weights; has shape (H, D) b1: First layer biases; has shape (H,)

```
W2: Second layer weights; has shape (C, H)
    b2: Second layer biases; has shape (C,)
    Inputs:
    - input size: The dimension D of the input data.
    - hidden_size: The number of neurons H in the hidden layer.
    - output size: The number of classes C.
    self.params = {}
    self.params['W1'] = std * np.random.randn(hidden_size, input_size)
    self.params['b1'] = np.zeros(hidden size)
    self.params['W2'] = std * np.random.randn(output_size,
hidden_size)
    self.params['b2'] = np.zeros(output_size)
  def loss(self, X, y=None, reg=0.0):
    Compute the loss and gradients for a two layer fully connected
neural
    network.
    Inputs:
    - X: Input data of shape (N, D). Each X[i] is a training sample.
    - y: Vector of training labels. y[i] is the label for X[i], and
each y[i] is
      an integer in the range 0 \le y[i] < C. This parameter is
optional; if it
      is not passed then we only return scores, and if it is passed
then we
      instead return the loss and gradients.
    - reg: Regularization strength.
    Returns:
    If y is None, return a matrix scores of shape (N, C) where
scores[i, c] is
    the score for class c on input X[i].
    If y is not None, instead return a tuple of:
    - loss: Loss (data loss and regularization loss) for this batch of
training
      samples.

    grads: Dictionary mapping parameter names to gradients of those

      with respect to the loss function; has the same keys as
self.params.
    # Unpack variables from the params dictionary
    W1, b1 = self.params['W1'], self.params['b1']
    W2, b2 = self.params['W2'], self.params['b2']
```

```

class TwoLayerNet(object):
  A two-layer fully-connected neural network with ReLU nonlinearity
and
  softmax loss that uses a modular layer design. We assume an input
dimension
  of D, a hidden dimension of H, and perform classification over C
classes.
  The architecure should be affine - relu - affine - softmax.
 Note that this class does not implement gradient descent; instead,
it
 will interact with a separate Solver object that is responsible for
running
  optimization.
  The learnable parameters of the model are stored in the dictionary
  self.params that maps parameter names to numpy arrays.
  .....
  def init (self, input dim=3*32*32, hidden dims=100,
num classes=10,
               dropout=0, weight scale=1e-3, reg=0.0):
    .....
    Initialize a new network.
    Inputs:
    - input_dim: An integer giving the size of the input
    - hidden_dims: An integer giving the size of the hidden layer
```

```
- num classes: An integer giving the number of classes to classify
   - dropout: Scalar between 0 and 1 giving dropout strength.
   - weight scale: Scalar giving the standard deviation for random
     initialization of the weights.

    reg: Scalar giving L2 regularization strength.

   self.params = {}

   Inputs:
   X: Array of input data of shape (N, d_1, ..., d_k)
   - y: Array of labels, of shape (N,). y[i] gives the label for
X[i].
   Returns:
   If y is None, then run a test-time forward pass of the model and
return:
```

```
- scores: Array of shape (N, C) giving classification scores,
where
     scores[i, c] is the classification score for X[i] and class c.
   If y is not None, then run a training-time forward and backward
pass and
   return a tuple of:

    loss: Scalar value giving the loss

    grads: Dictionary with the same keys as self.params, mapping

parameter
     names to gradients of the loss with respect to those parameters.
   .....
   scores = None
   # YOUR CODE HERE:
      Implement the forward pass of the two-layer neural network.
Store
      the class scores as the variable 'scores'. Be sure to use the
layers
      you prior implemented.
   hidden, cache1 = affine_relu_forward(X, self.params["W1"],
self.params["b1"])
   scores, cache2 = affine_forward(hidden, self.params["W2"],
self.params["b2"])
   #
   # END YOUR CODE HERE
   # If y is None then we are in test mode so just return scores
   if y is None:
     return scores
   loss, grads = 0, \{\}
   #
   # YOUR CODE HERE:
      Implement the backward pass of the two-layer neural net.
Store
      the loss as the variable 'loss' and store the gradients in the
      'grads' dictionary. For the grads dictionary, grads['W1']
holds
      the gradient for W1, grads['b1'] holds the gradient for b1,
```

```
etc.
        i.e., grads[k] holds the gradient for self.params[k].
    #
        Add L2 regularization, where there is an added cost
    #
0.5*self.reg*W^2
        for each W.
    #
                     Be sure to include the 0.5 multiplying factor to
    #
        match our implementation.
    #
    #
        And be sure to use the layers you prior implemented.
#
    l, g = softmax_loss(scores, y)

    dldx1, grads["W1"], grads["b1"] = affine_relu_backward(dldx2,
cache1)
    loss = l + reg_loss
    grads["W1"] += self.reg * self.params["W1"]
    grads["W2"] += self.reg * self.params["W2"]
#
    # END YOUR CODE HERE
#
    return loss, grads
class FullyConnectedNet(object):
  A fully-connected neural network with an arbitrary number of hidden
layers,
  ReLU nonlinearities, and a softmax loss function. This will also
implement
  dropout and batch normalization as options. For a network with L
layers,
  the architecture will be
  {affine - [batch norm] - relu - [dropout]} x (L - 1) - affine -
softmax
  where batch normalization and dropout are optional, and the {...}
block is
  repeated L - 1 times.
```

Similar to the TwoLayerNet above, learnable parameters are stored in the self.params dictionary and will be learned using the Solver class. def \_\_init\_\_(self, hidden\_dims, input\_dim=3\*32\*32, num\_classes=10, dropout=0, use batchnorm=False, reg=0.0, weight scale=1e-2, dtype=np.float32, seed=None): ..... Initialize a new FullyConnectedNet. Inputs: - hidden\_dims: A list of integers giving the size of each hidden laver. input\_dim: An integer giving the size of the input. - num\_classes: An integer giving the number of classes to classify. - dropout: Scalar between 0 and 1 giving dropout strength. If dropout=0 then the network should not use dropout at all. use batchnorm: Whether or not the network should use batch normalization. - reg: Scalar giving L2 regularization strength. - weight\_scale: Scalar giving the standard deviation for random initialization of the weights. - dtype: A numpy datatype object; all computations will be performed using this datatype. float32 is faster but less accurate, so you should use float64 for numeric gradient checking. seed: If not None, then pass this random seed to the dropout lavers. This will make the dropout layers deteriminstic so we can gradient check the model. ..... self.use batchnorm = use batchnorm self.use\_dropout = dropout > 0 self.reg = reg self.num layers = 1 + len(hidden dims) self.dtype = dtype self.params = {} # # YOUR CODE HERE: Initialize all parameters of the network in the self.params dictionary. The weights and biases of layer 1 are W1 and b1; and in

general the

```
weights and biases of layer i are Wi and bi. The
       biases are initialized to zero and the weights are initialized
       so that each parameter has mean 0 and standard deviation
weight scale.
